**CHAPTER 5: THREADS** 

OPERATING SYSTEMS (CS-220) SPRING 2021, FAST NUCES

**COURSE SUPERVISOR: ANAUM HAMID** 

anaum.hamid@nu.edu.pk

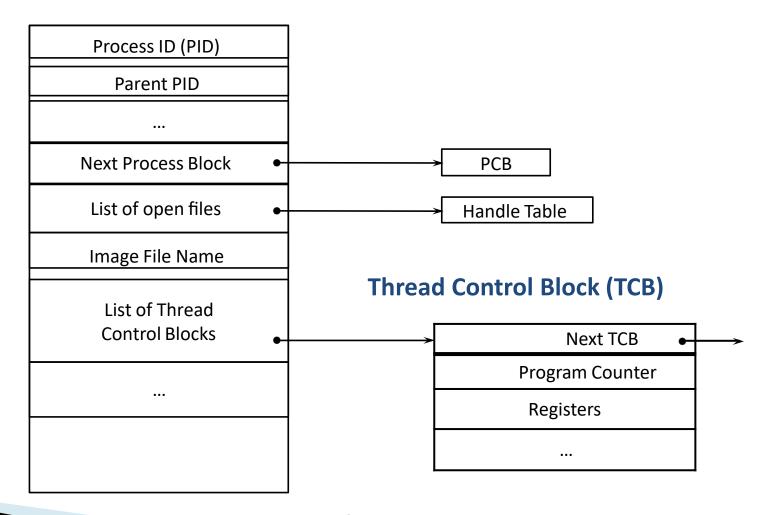

## **Process Concept**

- Processes are executed programs that have ...
  - Resource Ownership
    - Process includes a virtual address space to hold the process image
    - Operating system prevents unwanted interference between processes
  - Scheduling/Execution
    - Process follows an execution path that may be interleaved with other processes
    - Process has an execution state (Running, Ready, etc.) and a dispatching priority and is scheduled and dispatched by the operating system
- Today, the unit of dispatching is referred to as a thread or lightweight process
- The unit of resource ownership remains the process or task

#### **Control Blocks**

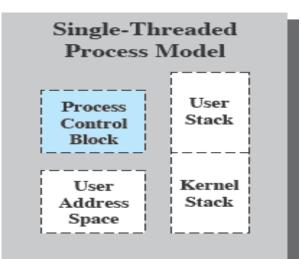

- Information associated with each process: Process Control Block
  - 1. Memory management information
  - 2. Accounting information
- Information associated with each thread: Thread Control Block
  - 1. Program counter
  - 2. CPU registers
  - 3. CPU scheduling information
  - 4. Pending I/O information

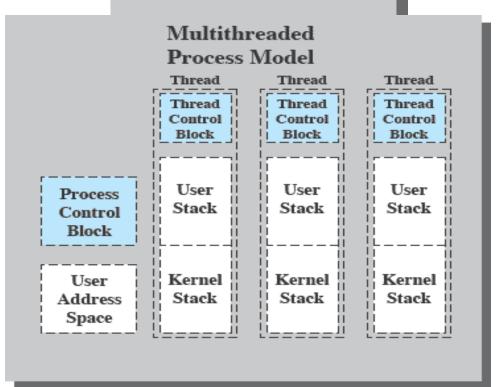

## **Control Blocks**

#### Single & Multithreading Process

- Each thread has
  - An execution state (Running, Ready, etc.)
  - Saved thread context when not running
  - An execution stack
  - Some per-thread static storage for local variables
  - Access to the memory and resources of its process (all threads of a process share this)
- Suspending a process involves suspending all threads of the process
- Termination of a process terminates all threads within the process

# Process Vs. Threads

S.N.	Process	Thread
1.	Process is heavy weight or resource intensive.	Thread is light weight taking lesser resources than a process.
2.	Process switching needs interaction with operating system.	Thread switching does not need to interact with operating system.
3.	In multiple processing environments each process executes the same code but has its own memory and file resources.	All threads can share same set of open files, child processes.
4.	If one process is blocked then no other process can execute until the first process is unblocked.	While one thread is blocked and waiting, second thread in the same task can run.
5.	Multiple processes without using threads use more resources.	Multiple threaded processes use fewer resources.
6.	In multiple processes each process operates independently of the others.	One thread can read, write or change another thread's data.

Course Supervisor: ANAUM HAMID

## Why Multithreading

#### Advantages

- Better responsiveness dedicated threads for handling user events
- Simpler resource sharing all threads in a process share same address space
- Utilization of multiple cores for parallel execution
- Faster creation and termination of activities

#### Disadvantages

- Coordinated termination
- Signal and error handling

Thread A (Process 1)

Thread B (Process 2)

Time quantum expires

Process created

Blocked

Ready

Running

 Reentrant vs. non-reentrant system calls: reentrant if it can be interrupted in the middle of its execution, and then be safely called again

#### **Thread States**

- The typical states for a thread are running, ready, blocked
- Typical thread operations associated with a change in thread state are:
  - SPAWN: a thread within a process may spawn another thread
    - Provides instruction pointer and arguments for the new thread
    - New thread gets its own register context and stack space
  - BLOCK: a thread needs to wait for an event
    - Saving its user registers, program counter, and stack pointers
  - UNBLOCK: When the event for which a thread is blocked occurs
  - FINISH: When a thread completes, its register context and stacks are deallocated.

Course Supervisor: ANAUM HAMID

## Thread Dispatching

#### **Threads**

#### Threads share....

- Global memory
- Process ID and parent process ID
- Controlling terminal
- Process credentials (user)
- Open file information
- Timers
- . . . . . . . .

## Threads specific Attributes....

- n Thread ID
- n Thread specific data
- n CPU affinity
- n Stack (local variables and function call linkage information)
- n .....

#### **Benefits**

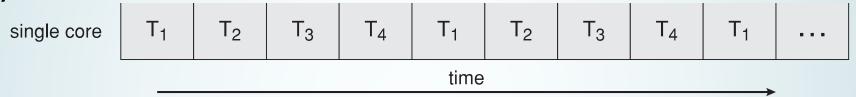

- Responsiveness One thread may provide rapid response while other threads are blocked or slowed down doing intensive calculations.
- Resource Sharing By default threads share common code, data, and other resources, which allows multiple tasks to be performed simultaneously in a single address space.
- **Economy** Creating and managing threads ( and context switches between them ) is much faster than performing the same tasks for processes.
- Scalability Utilization of multiprocessor architectures A single threaded process can only run on one CPU, no matter how many may be available, whereas the execution of a multi-threaded application may be split amongst available processors.

## Multicore Programming

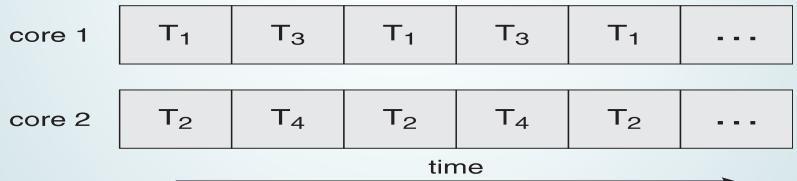

- A recent trend in computer architecture is to produce chips with multiple cores, or CPUs on a single chip.
- Parallelism implies a system can perform more than one task simultaneously
- Concurrency supports more than one task making progress
  - Single processor / core, scheduler providing concurrency

## Concurrency vs. Parallelism

 Concurrent execution on single-core system:

Parallelism on a multi-core system:

## Types of Parallelism

## Data vs. Task Parallelism

Data Parallelism	Task Parallelism
Same operations are performed on different subsets of same data.	Different operations are performed on the same or different data.
Synchronous computation	Asynchronous computation
Speedup is more as there is only one execution thread operating on all sets of data.	Speedup is less as each processor will execute a different thread or process on the same or different set of data.
Amount of parallelization is proportional to the input data size.	Amount of parallelization is proportional to the number of independent tasks to be performed
Designed for optimum load balance on multi processor system.	Load balancing depends on the availability of the hardware and scheduling algorithms like static and dynamic scheduling.

#### Amdahl's Law

gives the theoretical <u>speedup</u> in <u>latency</u> of the execution of a task at fixed <u>workload</u> that can be expected of a system whose resources are improved

$$speedup \le \frac{1}{S + \frac{(1-S)}{N}}$$

Where S = portion of program executed serially N = Processing Cores

## Amdahl's Law Example

we have an application that is 75 percent parallel and 25 percent serial. If we run this application on a system with two processing

cores?

S=25%=0.25, N=2

If we add two additional cores, calculate speedup?

## Types of Threads

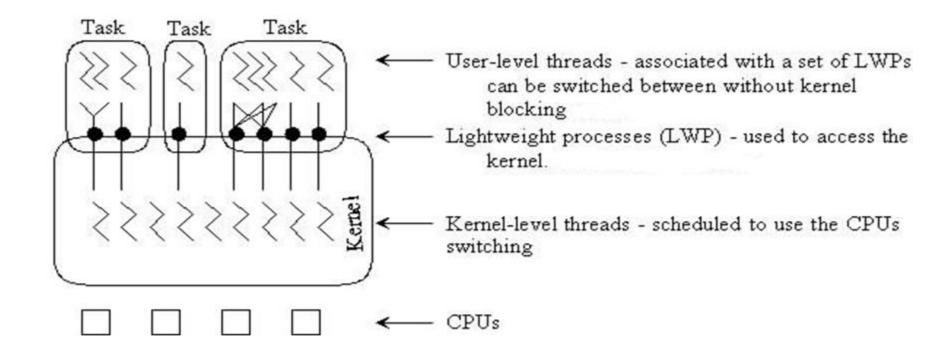

Support provided at either

- User level -> user threads
  Supported above the kernel and managed without kernel support
- Kernel level -> kernel threads
  Supported and managed directly by the operating system

What is the relationship between user and kernel threads?

Course Supervisor: ANAUM HAMII

#### User vs. Kernel Thread

Course Supervisor: ANAUM HAMID

## **User Threads**

- Thread management done by user-level threads library
- Three primary thread libraries:
  - POSIX Pthreads
  - Win32 threads
  - Java threads

Course Supervisor: ANAUM HAMID

#### Kernel Threads

- Supported by the Kernel
- Examples
  - Windows XP/2000
  - Solaris
  - Linux
  - Tru64 UNIX
  - Mac OS X

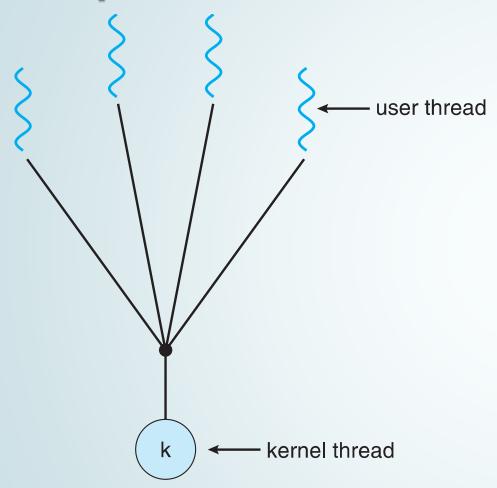

## Multithreading models

In a specific implementation, the user threads must be mapped to kernel threads, using these listed below Multithreading Models:

- Many-to-One
- 2. One-to-One
- 3. Many-to-Many

User Thread - to - Kernel Thread

## Many-to-One

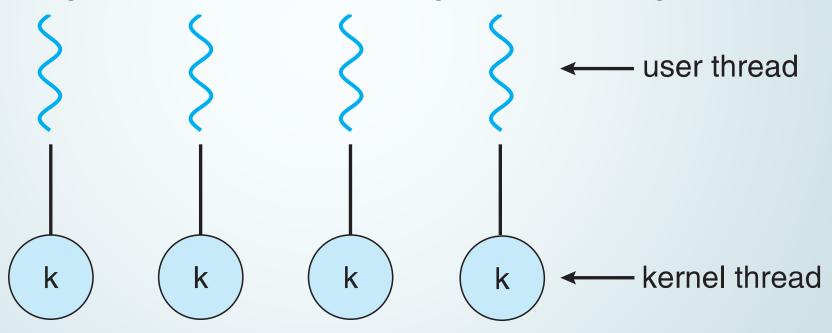

## Many user-level threads mapped to single kernel thread

- Only one thread can access the kernel at a time,
- multiple threads are unable to run in parallel on multicore systems.
- the entire process will block if a thread makes a blocking system call

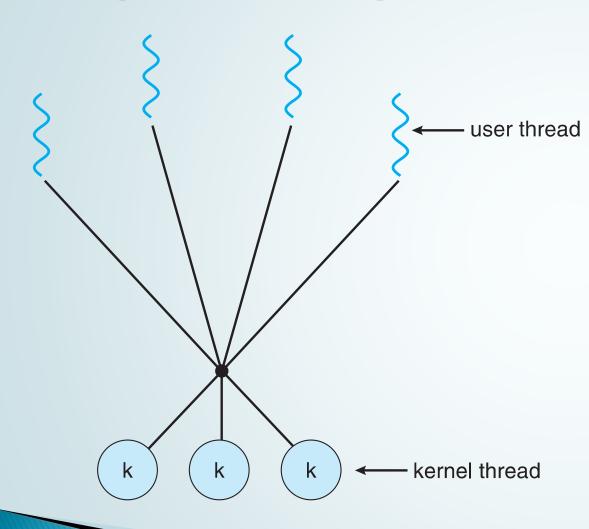

#### One-to-One

#### Each user-level thread maps to kernel thread

- more concurrency than the many-to-one model by allowing another thread to run when a thread makes a blocking system call.
- Allows multiple threads to run in parallel on multiprocessors.
- drawback is, creating a user thread requires creating the corresponding kernel thread

## Many-to-Many Model

- multiplexes many user-level threads to a smaller or equal number of kernel threads
- developers can create as many user threads as necessary, and the corresponding
- kernel threads can run in parallel on a multiprocessor.
- When thread performs a blocking system call, the kernel can schedule another thread for execution.

#### **Thread Libraries**

- Three main thread libraries in use today:
  - POSIX Pthreads
    - May be provided either as user-level or kernel-level
    - A POSIX standard (IEEE 1003.1c) API for thread creation and synchronization
    - API specifies behavior of the thread library, implementation is up to development of the library
  - Win32
    - Kernel-level library on Windows system
  - Java
    - Java threads are managed by the JVM
    - · Typically implemented using the threads model provided by underlying OS

## POSIX Compilation on Linux

On Linux, programs that use the Pthreads API must be compiled with

-pthread or -lpthread

gcc -o thread -lpthread thread.c

#### POSIX: Thread Creation

int pthread\_create(pthread\_t \*thread, const pthread\_attr\_t \*attr, void
\*(\*start)(void \*), void \*arg);

- \*\*thread Is the location where the ID of the newly created thread should be stored, or NULL if the thread ID is not required.
- \* attr Is the thread attribute object specifying the attributes for the thread that is being created. If attr is NULL, the thread is created with default attributes.
- start Is the main function for the thread; the thread begins executing user code at this address.
- arg Is the argument passed to start.

## POSIX: Thread ID

```
#include <pthread.h>
pthread_t pthread_self()
```

returns: ID of current (this) thread

## POSIX: Wait for Thread Completion

```
#include <pthread.h>
pthread_join (thread, NULL)

returns: 0 on success, some error code on failure.
```

#### POSIX: Thread Termination

```
#include <pthread.h>
Void pthread_exit (return_value)
```

Threads terminate in one of the following ways:

- 1. The thread's start functions performs a return specifying a return value for the thread.
- Thread receives a request asking it to terminate using pthread\_cancel()
- Thread initiates termination pthread\_exit()
- 4. Main process terminates

```
int main()
2.
      pthread_t thread1, thread2; /* thread variables */
3.
      thdata data1, data2;
                             /* structs to be passed to threads */
4.
5.
      /* initialize data to pass to thread 1 */
6.
      data1.thread_no = 1;
7.
      strcpy(data1.message, "Hello!");
8.
      /* initialize data to pass to thread 2 */
9.
      data2.thread_no = 2;
10.
      strcpy(data2.message, "Hi!");
11.
12.
      /* create threads 1 and 2 */
13.
      pthread_create (&thread1, NULL, (void *) &print_message_function, (void *) &data1);
14.
      pthread_create (&thread2, NULL, (void *) &print_message_function, (void *) &data2);
15.
      /* Main block now waits for both threads to terminate, before it exits
16.
        If main block exits, both threads exit, even if the threads have not
17.
        finished their work */
18.
      pthread_join(thread1, NULL);
19.
      pthread_join(thread2, NULL);
20.
21.
22. exit(0);
                                                                       Example code but not complete
23. }
```

## Implicit Threading

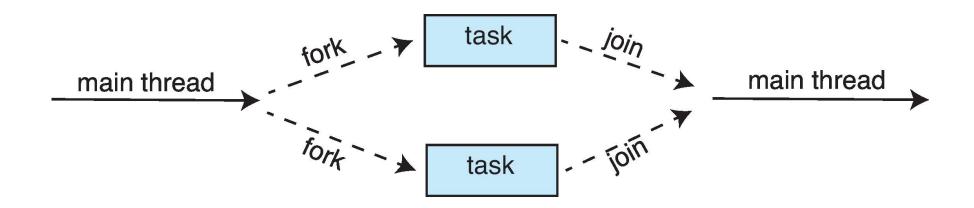

- Creation and management of threads done by compilers and run-time libraries rather than programmers
- These listed below methods explored
  - 1. Thread Pools
  - 2. Fork Join
  - 3. OpenMP

#### **Thread Pools**

- Create a number of threads in a pool where they await work
- Advantages:
  - Usually slightly faster to service a request with an existing thread than create a new thread
  - Allows the number of threads in the application(s) to be bound to the size of the pool

## Fork-Join Parallelism

Multiple threads (tasks) are forked, and then joined.

#### **OpenMP**

- An Application Program Interface (API) that may be used to explicitly direct multithreaded, shared memory parallelism
- Three main API components
  - Compiler directives
  - Runtime library routines
  - Environment variables
- Portable & Standardized
  - API exist both C/C++ and Fortan 90/77
  - Multi platform Support (Unix, Linux etc.)

## **OpenMP Compilation**

• GCC

bash: \$ gcc -fopenmp hi-omp.c -o hi-omp.x

Course Supervisor: ANAUM HAMID

#### **OpenMP Directives**

#pragma omp parallel default(shared) private(beta,pi)

#### **#pragma omp barrier**

Each thread waits at the barrier until all threads have reached it.

#### **#pragma omp for**

Distributes the iterations of a loop over multiple threads

Course Supervisor: ANAUM HAMID

## OpenMP threads

- Thread Creation:
- omp\_get\_num\_threads()

Returns number of threads in parallel region Returns 1 if called outside parallel region

- Thread Id:
- omp\_get\_thread\_num()
- ▶ Returns id of thread in team Value between [0,n-1] // where n
  - = #threads Master thread always has id 0

## Open MP Example

```
OpenMP include file
#include "omp.h" <
void main()
                Parallel region with default
                                          Sample Output:
                number of threads
                                          hello(1) hello(0) wor
#pragma omp parallel
                                          world(0)
   int ID = omp get thread num();
                                          hello (3) hello(2) wor
   printf(" hello(%d) ", ID);
                                          world(2)
   printf(" world(%d) \n", ID);
                                       Runtime library function to
        End of the Parallel region
                                       return a thread ID.
```

Course Supervisor: ANAUM HAMID

## Thread-Local Storage

- Thread-local storage (TLS) allows each thread to have its own copy of data.
- major thread libraries (pThreads, Win32, Java) provide support for thread-specific data, known as thread-local storage or TLS.

## Signal Handling

- Signals are used in UNIX systems to notify a process that a particular event has occurred.
- A signal handler is used to process signals
  - 1. Signal is generated by particular event
  - 2. Signal is delivered to a process
  - 3. Signal is handled by one of two signal handlers:
    - 1. default
    - 2. user-defined
- Where should a signal be delivered for multi-threaded?
  - 1. Deliver the signal to the thread to which the signal applies
  - 2. Deliver the signal to every thread in the process
  - 3. Deliver the signal to certain threads in the process
  - 4. Assign a specific thread to receive all signals for the process

#### THREAD SCHEDULING

- In systems that support user and kernel-level threads, kernel-level threads are scheduled by the OS.
- Kernel-level threads instead of processes are scheduled.
- User-level threads are managed by a thread library.
- To run on the CPU, the user-level thread must be mapped on an associated kernel-level thread

#### Contention Scope - Kernel Thread scheduling

- On systems implementing the many-to-one and many-tomany models, the thread library schedules user-level threads to run on an available LWP. This scheme is known as process contention scope (PCS),
- (When we say the thread library schedules user threads onto available LWPs, we do not mean that the threads are running on a CPU. That would require the operating system to schedule the kernel thread onto a physical CPU.) To decide which kernel-level thread to schedule onto a CPU, the kernel uses systemcontention scope (SCS).

#### THANK YOU
